Vidyarthi Digital Literacy (NGMC)

The Digital Divide Within: From Basic Tools to Responsible Digital Citizenship

Individual Case Study Report

NAME: - SURYANSH PARTSP SINGH

REG NO: - 25BAI10845

BRANCH: -B-TECH CSE (AI/ML)

Section A: Establishing the Context

A.1 The Hidden Gap in Digital Fluency

We live in an era where a college student in India can launch a podcast, manage a GitHub repository, collaborate with teammates across cities through Google Docs, and apply for internships on LinkedIn all before noon. From the outside, this appears to be a portrait of digital competence. The question this case study forces us to confront, however, is a sharper and more uncomfortable one: does knowing how to operate a tool constitute understanding it.

The gap described in this case is not about access or even ability it is about awareness. Consider the difference between driving a car and understanding traffic law. Most people can drive without ever thinking about liability, right-of-way legislation, or the engineering of road signs. They operate within a system they have never had to examine. Digital tools work in precisely the same way. Platforms like Canva, Miro, and Google Slides have been designed specifically to make complexity invisible. Templates, drag-and-drop interfaces, and AI-assisted suggestions reduce the barrier to entry so far that a student can produce a visually polished presentation without writing a single original sentence or verifying a single fact.

This convenience, while democratising in some ways, creates a fundamental illusion: that ease of output implies depth of understanding. A student who can apply a Canva template may have no awareness of copyright licensing, no sense of how visual framing influences audience perception, and no understanding of what data Canva collects about them while they work. The tool has been used but the system behind it remains opaque.

A.2 The Illusion Reinforced by Abundance

The widespread availability of platforms has compounded this problem rather than solved it. When every student has a LinkedIn profile, GitHub repository, and Kaggle account, the pressure to participate increases but the pressure to participate thoughtfully does not increase with it. Participation becomes the signal of competence, regardless of what the participation actually contains.

This matters because digital platforms are not neutral. They are designed with specific incentive structures: likes, views, profile completion scores, follower counts. These metrics reward visibility and consistency of output, not accuracy or depth. A student whose LinkedIn shows ten certifications and five projects will appear more credible than one with two genuine, well-executed pieces of work even if the former has exaggerated every claim and the latter has produced original, rigorous work.

The result is what might be called the illusion of competence at scale. Students are not simply fooling recruiters or faculty they are often fooling themselves. When Arjun lists skills he has only briefly explored, he is not being consciously dishonest. He is behaving in accordance with the logic of the platform, which rewards the act of listing over the reality behind it.

A.3 Digital Participation vs. Digital Literacy

The distinction this case establishes is one between digital participation and digital literacy. Participation is observable: it is the act of being present on platforms, contributing to documents, sending emails, uploading repositories. Literacy is something different it is the capacity to understand consequences, evaluate risk, make ethical judgments, and communicate with appropriate intentionality.

Arjun participates in all the right digital spaces. He has the profiles, the repositories, the submission history. But as each episode of the case reveals the uneven group contribution, the unprofessional email, the phishing trap he lacks the reflective layer that would make that participation genuinely competent. He is not an outlier. He is, as the case carefully notes, representative of a broader pattern among students who are digitally active but not digitally aware.

Why does this matter? Because the consequences of digital decisions are not contained within the platform. A poorly judged email reaches a real person and shapes a real professional relationship. An exaggerated GitHub profile will eventually be tested in an interview. A phishing attack does not stay on screen it reaches into email accounts, bank credentials, and personal data. Digital literacy is not a soft skill for the modern world. It is a survival skill.

Section B: Digital Identity and Ethics.

B.1 The Case for Equal Opportunity and Its Limits

The most compelling argument in favour of digital platforms is democratic access. A student from a small town in Madhya Pradesh can, in theory, present skills on LinkedIn that are visible to a multinational recruiter in Mumbai or Singapore. GitHub doesn't ask for the name of your college before displaying your code. Kaggle doesn't care about your family's income. In this sense, these platforms genuinely reduce certain structural barriers that dominated the pre-digital job market.

However, this ideal of meritocratic visibility breaks down in practice for several reasons. First, the ability to present oneself well on digital platforms is itself a skill one that is unevenly distributed and highly correlated with prior exposure, coaching, and social capital. Students from elite institutions or well-networked backgrounds learn professional self-presentation earlier and more naturally. The platform is equal; the preparation for it is not.

Second, the signal value of platforms erodes as participation becomes universal. When every student has a LinkedIn, recruiters must look harder for differentiators and those differentiators tend to be things that money and mentorship can provide: premium memberships, endorsed skills, recommendation letters from known names. The democratising promise of digital platforms is real but partial.

B.2 Performance Over Authenticity

I believe the more pressing concern is not inequality of access but the culture of performance that digital platforms actively cultivate. Platforms like LinkedIn are not neutral showcases — they are designed with engagement mechanics that reward activity over quality. Profile completion bars, 'All-Star' badges, connection milestones all of these nudge users toward constant visible output.

In this environment, Arjun's behaviour is not a personal failing. It is a rational response to the incentive structure he has been placed in. If visibility is what recruiters appear to value, and visibility is what platforms measure, then optimising for visibility even at the expense of accuracy is the logical move. The platform has not asked him to be honest; it has asked him to be present.

This is the deeper problem. The culture of self-promotion that digital platforms have normalised makes it difficult for students to distinguish between what they actually know and what they have presented themselves as knowing. Over time, the curated version can begin to feel like the real one until an interview, a technical test, or a real project exposes the gap.

B.3 Misrepresentation: Ethics or Norm?

There is a seductive argument that exaggeration is simply 'how the game works that everyone embellishes on LinkedIn, and that it is naive to hold students to a stricter standard. I want to examine this argument seriously before rejecting it.

It is true that professional self-presentation has always involved selective emphasis. A resume is not a complete record; it is a curated document. Framing one's experience favourably is not the same as lying. However, the case of Arjun listing skills he has only briefly explored, uploading incomplete or copied code goes beyond selective framing. It involves presenting signals of competence that are designed to be interpreted as indicators of real ability.

The ethical issue is not about rigid rule-following. It is about the downstream consequences. When someone hires based on a misrepresented profile, they bear a cost. When a team relies on a claimed skill that doesn't exist, the team bears a cost. And when the student eventually faces a situation that requires the skill they claimed to have, they bear a cost. The normalisation of misrepresentation does not eliminate these consequences it just delays and diffuses them.

My position is that it is ethically wrong, even if it is common. Accepting something as a norm does not make it right. It makes it a problem that has not yet been adequately challenged.

B.4 Digital Permanence and Accountability

The final dimension of this section is perhaps the most philosophically interesting. Should students be held accountable for content posted when they lacked awareness. This is a genuinely hard question.

On one hand, holding individuals permanently accountable for the ignorance of their past seems harsh, particularly in a domain that has changed as rapidly as the digital world. A student who posted unverified answers on Stack Overflow at age nineteen did not necessarily intend to mislead — they were navigating a learning environment without adequate guidance.

On the other hand, digital permanence is not a new concept it is a documented feature of every platform. The terms of service for every major platform make clear that content, once posted, persists. Choosing not to think about this is itself a form of decision. The student who is 'surprised' that their old posts are visible chose, at every point, not to investigate how the platform works.

I think accountability should be contextual, but not absent. A recruiter reviewing an old, clearly amateur GitHub repository should weigh it against current evidence of growth. But the student who continues to let inaccurate or misleading content stand without correction, once they are aware, has moved beyond ignorance into something closer to negligence.

Section C: Collaboration vs. Misuse

C.1 What the Group Assignment Actually Measured

The group assignment episode is worth examining closely, because it illustrates something that is rarely discussed in conversations about digital collaboration tools: the tools fulfilled every technical promise, and the learning outcome still failed for several participants.

Google Docs and Slides worked as designed. Version conflicts were eliminated. Asynchronous contribution was enabled. The document was completed ahead of schedule. The group received high marks. By every measurable metric, the collaboration was a success.

And yet, when asked to explain the content they had nominally contributed to, several members could not. This is the central paradox of digital collaboration platforms: they are excellent at measuring output, and almost completely blind to process. What the platforms cannot see and therefore cannot record or reward is understanding.

C.2 The Strongest Argument for Unrestricted Collaboration

Let me construct the strongest version of the argument that digital collaboration should not be restricted. It runs as follows:

Collaboration is the dominant mode of knowledge work in the 21st century. Almost no significant professional output in technology, medicine, law, design, or research is produced by individuals working in isolation. Restricting digital collaboration in educational settings

therefore trains students for a world that doesn't exist. Google Docs teaches real-time co-authoring; Miro teaches distributed brainstorming GitHub teaches version-controlled collaborative coding. These are not shortcuts they are the actual skills employers want. A student who has navigated the social and technical complexity of group work on shared platforms has learned something genuinely valuable, even if the individual learning was uneven.

Moreover, restricting collaboration may disproportionately disadvantage students who thrive in collaborative learning environments versus solitary ones. The student who did most of the work in Arjun's group also learned something she learned how to carry a team, how to structure a group document, and how to meet a deadline under distributed conditions.
Dismissing this because others contributed less is too narrow a view of learning outcomes.

C.3 Why That Argument, Though Compelling, Is Incomplete

I find the above argument largely persuasive but only for collaboration in its genuine form. The problem in Arjun's case was not collaboration it was parasitic participation. One student doing the majority of the intellectual work, while others append their names and benefit equally from the outcome, is not collaboration. It is extraction.

The boundary between genuine collaboration and academic dishonesty is not inherently ambiguous it becomes ambiguous when platforms make individual contribution invisible. The solution is not to remove collaboration tools but to redesign how they are assessed.
Contribution logs, individual reflection submissions, peer evaluations, and oral follow-ups (as used in this case's class discussion) are all mechanisms that restore visibility to process without sacrificing the benefits of collaborative tools.

Does a digital environment make ethical behaviour harder to enforce? Yes but only if assessment remains anchored to the same metrics designed for paper-based, individual work. The problem is not the technology. The problem is that pedagogy has not kept pace with the tools it has adopted.

Section D: Cyber Awareness and Responsibility

D.1 Why Awareness Campaigns Alone Keep Failing

Arjun knew what phishing was. He had learned it in a classroom. He knew not to share login credentials. He knew to verify sources. And he did none of these things when it mattered.

This is not unusual. The cybersecurity industry has spent decades and billions of dollars on awareness campaigns, and phishing remains one of the most successful attack vectors in the world. The reason is not ignorance it is the gap between declarative knowledge (knowing what a thing is) and procedural behaviour (acting on that knowledge under pressure, in real time, when stakes feel high).

Arjun's situation involved several psychological conditions that attackers specifically engineer: urgency (limited slots, 12-hour deadline), desire (he had been actively applying for internships), and social proof (a professional logo, structured language, familiar format). These conditions do not simply override knowledge they activate cognitive shortcuts that are faster and more powerful than the slower, more deliberate reasoning that classroom learning trains.

This is why awareness campaigns that focus on listing warning signs are insufficient. A student who can recite five indicators of phishing in a classroom will not necessarily pause to run through that checklist when an exciting opportunity appears in their inbox. The knowledge must be trained as reflex, not just as information and that requires repeated exposure to realistic scenarios, not PowerPoint slides.

D.2 Who Bears Responsibility?

This is a question where I want to resist the easiest answer. The easiest answer is to blame the user: Arjun knew better, he should have checked, this is on him. The next easiest answer is to blame the system: platforms are poorly designed, institutions fail to prepare students, this is structural. The honest answer involves both.

Users bear genuine responsibility. Digital platforms are voluntarily adopted, and the risks they carry are not secret. A student who enters login credentials into an unverified third-party form has made a decision and decisions carry responsibility. The argument that urgency excuses the decision is not fully convincing; urgency is a condition, not an exonerator.

At the same time, platforms bear significant responsibility that is routinely underacknowledged. Email providers could flag messages with mismatched sender domains more visibly. Browsers could provide stronger warnings before form submissions to unverified sites. Institutions could build cyber safety practice not just awareness into curricula before students encounter real threats. The fact that Arjun encountered a phishing attempt without ever having practiced responding to a simulated one is a systemic failure, not just a personal one.

D.3 Negligence, Education, or Systemic Failure?

The scenario posed in the assignment asks whether a student falling for a scam should be classified as negligence, lack of education, or systemic failure. My answer is that these categories are not mutually exclusive and the response to the incident should address all three.

It is a moment of personal negligence: the warning signs were visible in retrospect, and the step of verification was skipped. It is also evidence of educational failure: the knowledge was present but was never trained into habitual behaviour. And it reflects a systemic failure: email infrastructure, platform design, and institutional preparation all contribute to an environment where these attacks succeed at scale.

Current preventive measures strong passwords, two-factor authentication, awareness guidelines — address the aftermath of a breach better than they prevent one. They are necessary but insufficient. The deeper behavioural issue that people act quickly when they feel urgency and desire requires an approach that trains decision-making under those exact psychological conditions. Until that gap is addressed, awareness will continue to lag behind behaviour in moments that actually matter.

Section E: Communication and Digital Etiquette

E.1 The Habit Overrides the Knowledge

Arjun's email Hi sir, I need recommendations urgently. Send asap. Was not written in ignorance of professional email format. He had almost certainly seen the correct structure at some point during his education. The problem is that knowledge of a format and habitual use of a format are different things.

Most of Arjun's digital communication the mode that has shaped his reflexes happens on WhatsApp, Instagram DMs, and Discord. These platforms reward brevity and speed. They are low-stakes environments where tone matters less than immediacy. Over hundreds or thousands of interactions, this communication style becomes automatic. When he opens his email client, his fingers and his instincts are still in WhatsApp mode.

This is not laziness it is a predictable consequence of context collapse, the phenomenon where different social contexts with different norms are experienced through the same device, using the same app (email), often in rapid succession. The mental switch from casual to formal requires deliberate effort, and in a moment of deadline pressure, that effort is often not made.

E.2 Is Informality Becoming the New Norm?

There is a growing argument in professional culture that informal communication is simply evolving norms that the formality of traditional professional correspondence was itself a class marker, and that its erosion reflects a healthier, more egalitarian workplace. Some companies now communicate entirely via Slack in a register indistinguishable from group chat.

I take this argument seriously, but with an important qualification. Norms are context-dependent. Within a team that has established a shared culture, informal communication can enhance psychological safety and speed. But first-contact communication an email to a faculty member you want a recommendation from, a message to an internship coordinator you have never met still operates under different rules, because the relationship has not yet been established.

Communication style in those moments does not just convey information it communicates an assessment of the relationship itself. 'Hi sir, send asap' does not simply request a recommendation; it signals that the writer has not considered the recipient's perspective, time, or status. The faculty member's cool, formal response was not an overreaction. It was an accurate reading of what the email implied about how Arjun viewed the interaction.

Students should therefore not be judged harshly for informal communication as a general rule but they should be held to a standard in contexts where the relationship and stakes demand

it. The problem is not that students communicate informally; it is that they have not developed the situational awareness to know when formality is called for Section F, Personal Reflection

Before working through this case study, my understanding of digital literacy was largely technical. I thought of it as knowing how to use tools efficiently navigating platforms, avoiding obvious scams, keeping passwords strong. It felt like something that could be measured by a checklist.

What this case study has shifted, more than anything, is the frame. Digital literacy is not a set of skills to acquire and tick off. It is an ongoing orientation a habit of pausing before acting, of asking 'what am I actually doing here and why. before clicking, posting, contributing, or sending.

The episode that made me genuinely uncomfortable was the phishing section not because I haven't heard of phishing, but because Arjun's response mirrors decisions I recognise in myself. When something looks like an opportunity and creates urgency, I also move faster than I should. I have clicked links before verifying. I have filled out forms before reading them. The case made clear that knowing about a risk and being protected from it are two different states, and I have been operating as if they were the same.

If I am honest about my own digital behaviour, I would say the area I most need to work on is the one this case study raises least explicitly: the quality of attention I bring to digital decisions. I check notifications frequently, often mid-task. I respond to messages quickly without always thinking about tone or context. I have posted content without thinking about how it would look to someone I hadn't imagined as a reader.

If I had to name one concrete change after this case study, it would be this: before sending any professional communication an email, a LinkedIn message, a request to a faculty member I will take sixty seconds to re-read it from the recipient's perspective. Not to check grammar, but to ask whether the message accurately represents the respect and seriousness with which I actually want to be seen. That is a small habit change. But as Arjun's case makes clear, it is exactly the kind of small habit change that distinguishes someone who uses digital tools from someone who understands them.

End
